Paper prepared for presentation at the “Innovative Applications of Traffic Control Devices for Safer Pedestrian and Cyclist Mobility” session

of the 2015 Conference of the
Transportation Association of Canada
Charlottetown, PEI
ABSTRACT

Pedestrians are the most vulnerable road users in transportation system. In 2013, Calgary witnessed 348 casualty (fatal and injury) collisions involving pedestrians. Accommodation of pedestrians at crosswalks in a safe and interactive manner has always been a great challenge. Amid the growing use of Rectangular Rapid Flashing Beacons (RRFBs) in the United States after FHWA approval (FHWA, 2008), there has been a significant amount of research conducted on the effectiveness of this device and technical specifications. However, there is very limited information in the Canadian context simply because of the lack of use of this device in Canada. The City of Calgary provided a research platform by piloting these devices at eight locations in 2012 to evaluate motorists’ yielding behavior to pedestrians and the reliability of RRFB’s solar powered battery system in Canadian weather. Following the encouraging study results presented to the City Council, Calgary decided to expand the RRFB installation to 25 locations by 2015.

In tune with the ‘Vulnerable Road User Safety Strategy’; one of the 11 strategies identified in Calgary Safer Mobility Plan 2013-2017, this device is expected to help in reducing pedestrian related collisions at crosswalks. Before-after studies conducted within the City for RRFB devices indicated that the level of motorists’ yield compliance to pedestrians increased significantly at pedestrian crossings from lower to mid 80% to over 95% in most cases.

It was concluded that given the significantly lower installation cost (approximately 1/3rd) compared to overhead flashers and yet similar results on yield compliance by motorists, this device could provide a cost-effective solution to improve pedestrian safety at crosswalks (both intersections and mid-block locations). The rapid flashing pattern of RRFBs appears to be very effective in catching driver’s attention thereby increasing motorists’ yield compliance to pedestrians at crosswalks. Increased yield compliance at significantly low cost provides an opportunity to overcome budget constraints. Versatile nature of this device with options to power by solar batteries or by connecting to permanent power grid provides a perfect opportunity to use this device in various climatic conditions, especially in Canadian context.

This paper presents the results of the before-after studies, lessons learned on the performance, powering the device and next steps for the use of this device. With the recent TAC approval of RRFB as a traffic control device, this device is expected to be used widely across Canada once the warrant process has been established.
INTRODUCTION

Calgary is one of the fastest growing cities in Canada with population over a million. With the diversity in population growth in recent years the City is facing enormous challenges to provide safe and credible pedestrian crossing facilities. Due to their vulnerability, pedestrians are more frequently injured or killed as compared to occupants of motor vehicles. In 2013, 348 injury and fatal collisions involving pedestrians occurred within the City of Calgary roads. During the same period, pedestrians were involved in 24% of fatal collisions and 13% of injury collisions while being involved in less than 1% of total collisions.

Transportation Association of Canada (TAC) has published a number of guidelines to improve pedestrian safety at crosswalks through the implementation of traffic control devices. However, there still exists a significant gap between a marked and signed crosswalk and a special crosswalk, in terms of structure and cost. After the interim approval of Rectangular Rapid Flashing Beacons (RRFB) by Federal Highway Administration (FHWA), a number of cities in the United States have started using RRFB as a pedestrian activated tool to reinforce signs and markings at pedestrian crossings to improve pedestrian safety. This device however, has not been commonly used in Canada because of the lack of Canadian Standards and implementation guidelines.

Despite the lack of Canadian guidelines, The Calgary City Council decided to undertake the RRFB Pilot Project in 2012 to assess motorist yielding behaviour and the performance of the solar power system. Funding in the amount of $200,000.00 for the RRFB Pilot Project was provided by the Mayor’s Innovation Fund. The goal of the project was to test new and innovative technology in Calgary conditions. Products from different vendors were used for pilot to gather information on their performance, although the intent was not to specifically compare products and pick one for future use. This pilot project, however, did provide crucial information to the project undertaken by the TAC to get approval of RRFB as a traffic control device.

ALIGNMENT WITH LOCAL & GLOBAL INITIATIVES

The RRFB pilot project falls under the category ‘Vulnerable Road Users Safety’; one of the 11 strategies of Calgary Safer Mobility Plan that aims to achieve 12 percent reduction in vulnerable road user casualty collision rate per 100,000 population. The baseline is 51.2 casualty collisions per 100,000 population based on the 3 year rolling average of 2009 to 2011, as shown in Figure 1. The RRFB pilot project aimed to contribute towards achieving the target set for the vulnerable road user safety strategy.
RRFB PILOT - PHASE 1 INSTALLATIONS

1. SITE SELECTION

Eight locations were chosen as part of the Phase 1 installations of the RRFB in 2012 and 2013. The pilot occurred over a one-year period, beginning in May 2012. In the absence of proper warrant process for selection of RRFB installation locations, a number of criteria were considered to make sure that the selected locations represent various traffic levels, speed limits, geometric characteristics and geographic conditions.

The traffic volumes at selected locations ranged from < 5,000 vehicles/day to approx. 15,000 vehicles/day. Speed limit at these locations varied from 30 km/h to 60 km/h. The selected locations included 2 freeway interchange ramps, 2 multi-lane arterials with concrete median, 2 multi lane arterials with wide grassy median and 2 collectors within school zone. All the RRFBs were installed at locations with existing signed and marked crosswalks. These locations were identified based on the history of citizen complaints related to pedestrian safety issues.

2. SELECTION OF RRFB DEVICES

Products from four different vendors were used in the Phase 1 pilot. All of these installations were solar powered. Figure 2 to Figure 4 show various types of RRFB devices installed in Calgary. To continue the dialogue with suppliers regarding the emerging technologies and the performance of solar powered batteries, The City of Calgary conducted a number of vendors’ forum following the Phase 1 installations.

Figure 4: Various types of RRFB devices used in Calgary as part of Phase 1 Pilot
EVALUATIONS

1. YIELD COMPLIANCE STUDY

The effectiveness of the RRFBs was evaluated based on before-and-after yielding compliance using staged crossings. The yielding compliance evaluation methodology was based on the procedure presented in the Federal Highway Administration (FHWA) publication entitled ‘Effects of Yellow Rectangular Rapid-Flashing Beacons on Yielding at Multilane Uncontrolled Crosswalks’ (Shurbutt & Van Houten, 2010).

Data were collected for each staged crossing when vehicles were present, during weekdays and sunny or overcast weather conditions. For each of the staged crossings the observer measured the following behaviours:

a. Yielding compliance:
   - Noted as yielding if vehicle stopped or slowed to allow pedestrian to cross.
   - Noted as not yielding if vehicle did not stop, but would have been able to do so safely. The ability to stop safely was determined based on the threshold distance calculated using the Institute of Transportation Engineers (ITE) signal formula and the posted speed on the approach.
   - For each crossing, all incompliant vehicles were noted as not yielding and the first yielding vehicle per lane was noted as yielding.

b. Yield location: The categories for the yield distance used in this study were: less than 3 m, more than 3 m but less than 6 m, more than 6 m but less than 10 m, more than 10 m but less than 15 m, more than 15 m but less than 20 m, more than 20 m but less than 30 m, more than 30 m.

c. Unsafe behaviours:
   - Attempts to pass a stopped/yielding vehicle
   - Hard braking behind a stopped/yielding vehicle
   - Vehicle/pedestrian conflicts involving evasive action taken by a driver or pedestrian
   - Pedestrian trapped at centerline/median

The staged crossings were conducted in a consistent manner as naturally as possible. The crosser approached the crosswalk and placed one foot in the crosswalk when the vehicle was beyond the threshold distance. If the driver made no attempt to stop, the pedestrian did not proceed to cross.

At each site the data collection was conducted in one direction of travel, either due to one-way traffic or location on an uncontrolled leg of a two-way stop-controlled intersection (which lends itself to data collection along the near-side approach). The data collection was the same for each site with 100 or more compliance samples collected during the before period and 100 or more
compliance samples collected during the after period. The 100 samples were collected during one day and split between the morning peak, lunch peak, and afternoon peak periods.

Study results indicated that the devices improved the yielding behaviour in all cases to between 90% and 100%. Yield compliance before and after the RRFB are summarized in Table 2. The majority of locations where the driver yielding behavior to pedestrians were already high (mid 70% to 90% in most cases), experienced a consistent increase to over 90% (up to 100% in some cases).

</tbody>
</table>

Yield distance graph (Figure 6) indicates that yielding within 10 m of the crosswalk increased by 18% after the installation of the RRFB devices. The highest increase from 20% to 33% occurred in the 3-6 m category. The increase in percentage of vehicles yielding within 10 m was evident in all single lane approaches. However, the same trend was not noticed in the multi-lane approaches. Based on the observations, the shift in yielding location was likely due to drivers making the decision to stop when in closer proximity of the crosswalk with the presence of an RRFB as compared to the baseline condition when the drivers at those situations would proceed
without stopping. The increase in yielding within 10 m of the crosswalk with a single lane approach is not likely to pose significant safety concerns to pedestrians.

Figure 5: Graphs indicating yield compliance by motorists

The stopping location is of most concern with the multi-lane approaches when the stopped vehicle blocks the sight lines between a pedestrian and a vehicle in the adjacent lane. However, yielding within 10 m of the crosswalk decreased in the after period along multi-lane approaches which further improves the safety of pedestrians.

Figure 6: Yield distance
A follow up yield compliance study conducted in June 2014 to examine the effectiveness of these devices after a year in operation revealed that the RRFB continues to be highly effective in increased ‘yield to pedestrian’ compliance levels by motorists.

2. CONFLICT ANALYSIS

Unsafe behaviors that constitute conflicts with the pedestrians were recorded. Common types of conflicts noted were:

- Attempts to pass a stopped/yielding vehicle,
- Hard braking behind a stopped/yielding vehicle,
- Vehicle/pedestrian conflicts involving evasive action taken by a driver or pedestrian, and
- Pedestrian trapped at centerline/median

There was one incidence of a vehicle attempting to pass a stopped/yielding vehicle during the before period and none observed during the after period. However, there were several incidences of hard braking behind a stopped/yielding vehicle at three locations:

- At Glenmore Trail and 18 Street ramp two vehicles engaged in hard braking during the before period and four vehicles during the after period.
- At Crowchild Trail and Shaganappi Trail ramp two vehicles engaged in hard braking during the before period and two vehicles during the after period.
- At Sun Valley Blvd and Sun Harbour Road three vehicles engaged in hard braking during the before period and none during the after period.

However, these results were not statistically significant as the number of occurrences was too low for statistical analysis. There were no incidences of conflicts involving evasive action taken by a driver or pedestrian or pedestrians trapped at centerline/median during that data collection.

3. COLLISION ANALYSIS

Before-after collision analysis was not feasible as part of the pilot project reporting in 2013 because of the unavailability of two years of before-after collision data. As the pilot project was completed in 2012-2013, two years of before collision data (2010-2011) and two years of after collision data (2014-2015) will be used to perform the collision analysis when required collision data are available.

As part of the before-after analysis, collisions involving pedestrians will be compared before and after RRFB installations. The change in collision numbers at the study locations will be compared to a test site with similar characteristics to remove the bias. To account for the other conflicts such as hard braking, before-after comparison of rear end collisions will also be conducted.
4. FUNCTIONALITY/TECHNICAL ASPECTS

All RRFB installed as part of the Phase 1 pilot used solar power. An important component of this pilot project was to assess the functionality of the solar power systems in Calgary’s winter weather. The RRFBs were tested at each location after a period of cold weather (below -20 degrees Celsius). Testing was conducted during daytime and included activating the flasher for 20 cycles. A video of the flashing beacon was taken before and after the 20 flasher activations to assess any visual degradation in intensity and flashing time measurements. The functionality tests did not reveal any major concerns.

Maintenance and functionality of each installation were monitored. Regular monthly maintenance schedules were performed throughout the winter months and additional trouble calls were documented. Table 3 provides a summary of common issues and repairs completed during regular monthly maintenance as well as incidents reported by the citizens.

Reliability of solar power was one of the major concerns. The importance of reliable power source to maintain pedestrian safety is critical at all times. Although the manufacturers proposed innovative solutions to improve the reliability of solar batteries, The City of Calgary has decided to continue investigations with the following alternatives.

Connecting to Permanent AC Power:
This option eliminates the need for battery maintenance which historically has been the most significant negative aspect to solar power devices. Batteries require regular monthly maintenance and have a relatively short life cycle. The approximate cost to provide power to the existing and future units would be $10,000 – $25,000, variable depending on location.
Connecting to Streetlight Power:
This option uses streetlight power to supplement the solar power used to recharge batteries. As streetlights are only powered at night, this recharging will occur overnight. There are challenges with connecting to streetlight power, including conforming to the Canadian Electrical Code and existing capacity constraints. Further investigation will be conducted to determine the feasibility of connecting to streetlight power. This solution may only be feasible at specific locations.

Retrofitting with Automatic Alarms:
This option involves installing a device that triggers delivery of an email to the maintenance team if an RRFB’s battery voltage is low. This device would decrease maintenance response times and would increase the device reliability by ensuring shorter and fewer disruptions to their function. There would be an added costs associated with device installation as well as possible increases in maintenance costs. However, the maintenance costs would reflect actual needs as opposed to needs determined from complaints or monthly checks.

5. COSTS COMPARISON

Typical cost of a complete system with two sides (no median island RRFB) including poles and installation:

Solar: $15,000 - $20,000
AC system: $25,000 – $40,000
Hybrid system: $25,000 - $40,000 (i.e. wireless communication across the street with AC power or AC backup, but will provide similar reliability to an AC system for power and the versatility of a solar system).

In comparison, a typical special crosswalk (based on City of Calgary estimates) with a continuous power supply is approximately $85,000. This indicates that RRFB could provide a cost effective alternative to the traditional special crosswalk.
PHASE 2 INSTALLATIONS

After presenting the Phase 1 report to the City Council in 2013, City of Calgary decided to extend the pilot to total 25 locations by 2015. The positive results from Phase 1 study also garnered attention and support from the City Councillors and concerned citizens. A few installations have already been completed as part of the Phase 2. Figure 7 shows a new installation at Bowness Road NW.

One of the main differences of the new RRFB installations compared to the Phase 1 is the placement of the flashing beacons. Initially, the beacons were installed below the Pedestrian Crosswalk Sign (RA-4). However, the new installations have the flashing beacon above the sign. A study conducted by Fitzpatrick et al, 2014 also indicated that placing the flashing beacons above the signs increases drivers’ ability to detect an object moving on the crosswalk.

As solar power continues to be the dominating source for powering the RRFB batteries, the City of Calgary has decided to connect RRFBs to permanent AC power at four locations in 2015. Monitoring and evaluation of the performance of this device will continue for years to come.
FURTHER RESEARCH

City of Calgary plans to continue research on the performance of the RRFB in coming years to ensure the reliability of this device in terms of operational and technical performance. Discussions are underway with the University of Calgary to involve the graduate and postgraduate students in a more scientific research.

The main goal of using this device is to reduce pedestrian vehicle conflicts and hence provide safer road crossing opportunities for the vulnerable road users. A before-after collision analysis will be conducted after 2015 collision data is available; which will provide critical information on the effectiveness of this device in reducing the frequency or severity of collisions.

In addition, The City of Calgary has initiated before-after yield compliance study for a few special crosswalks. These results can be compared with the results from the RRFB yield compliance study to get an idea of the relative performance of these two types of traffic control devices.

LESSONS LEARNED

Some of the lessons learned from the RRFB pilot are summarized below:

1. RRFBs are very popular devices in Calgary among the citizens and City Councillors. This indicates a potential strong desire and political will to invest more in this device in coming years. A warrant procedure needs to be developed as soon as possible to ensure consistent application before too many RRFBs are installed.

2. The RRFBs are very effective in getting drivers’ attention. This could help significantly in reducing the vehicle-pedestrian conflict on the crosswalks.

3. How to power the RRFBs is still a matter of concern as the solar power doesn’t seem to be very reliable in winter conditions.

4. The effectiveness of RRFBs appears to be minimal when the approach angle is too low along curves.

CLOSING REMARKS/NEXT STEPS

Although a variety of traffic control devices are being used in Canada to improve safety of pedestrians at crosswalks, the Rectangular Rapid Flashing Beacons seem to be a very promising measure to address safety concerns at a very reasonable cost. The rapid flash pattern of this innovative device is able to better attract drivers’ attention, thereby increasing the yield compliance by the motorists.

Despite the popularity of the RRFB in the United States especially after FHWA provided interim approval for the use of this device, Canadian cities have not yet embraced the use of RRFB as traffic control device. This is likely due to the lack of uniform application guidelines and warrant procedures that are yet to be developed.
Striving for innovation, continuous improvement and finding cost effective alternatives, The City of Calgary undertook the investigation on the performance of the RRFB in terms of effectiveness (operational and technical) through this pilot project. With the encouraging yield performance results, The City of Calgary has decided to further extend the pilot. The Phase 1 pilot provided an opportunity to test the device in the Canadian context and garnered a lot of critical information that provided a platform for the study led by TAC in 2014. As a result, the RRFB is now a TAC approved traffic control device.

With the recent TAC approval of the RRFB as a traffic control device, it is expected that once the warrant procedure is developed, Canadian cities will start using this device where appropriate. Given the similarity of winter weather in Canadian jurisdictions, results of this pilot study are expected to be directly transferable to other jurisdictions throughout Canada.
